Introduction to BabyAGI

BabyAGI is an experimental framework designed to facilitate the development of autonomous AI agents through task planning. Created by Yohei Nakajima, BabyAGI aims to simplify the process of creating AI agents capable of self-building and autonomous operation. The core idea behind BabyAGI is to create an AI agent that can autonomously plan, execute, and learn from tasks using a simple yet effective architecture.

BabyAGI utilizes a function framework known as *functionz* that helps in storing, managing, and executing functions. This system allows for automatic loading of necessary functions based on task requirements, comprehensive logging capabilities that track function execution, errors, and interactions, and a dashboard for monitoring function executions, managing functions, and configuring triggers.

Functions within BabyAGI can be registered with dependencies and metadata, and they can be executed autonomously according to the defined triggers and conditions. This setup enables BabyAGI to handle complex workflows and tasks without constant human intervention.

Getting Started with BabyAGI

To explore and use BabyAGI, users have two main options:

Hosted Version

Access the hosted version of BabyAGI at Vercel to utilize the pre-configured environment and dashboard: [BabyAGI Hosted Version](#).

Local Installation

For local installation, first, clone the repository from GitHub:

```
git clone https://github.com/yoheinakajima/babyagi
```

Navigate to the project directory:

```
cd babyagi
```

Install the required dependencies:

```
pip install -r requirements.txt
```

Start the application:

```
python main.py
```

Finally, access the dashboard by navigating to:

```
http://localhost:8080/dashboard
```
